1 **Abstract**

2 **Objectives:** This study aimed to provide an up-to-date summary of the literature on flow in
3 elite sport, specifically relating to: (i) how flow is experienced; (ii) how these states occur;
4 and (iii) the potential controllability of flow.

5 **Design:** Systematic review.

6 **Methods:** A comprehensive literature search of SPORTdiscus, PsycINFO, SAGE journals
7 online, INGENTA connect, and Web of Knowledge was completed in August, 2011, and
8 yielded 17 empirical studies published between 1992 and 2011. The primarily qualitative
9 findings were analysed thematically and synthesised using a narrative approach.

10 **Results:** Findings indicated that: (i) some flow dimensions appear to be experienced more
11 consistently than others; (ii) key factors were consistently reported to induce or inhibit flow
12 occurrence; and (iii) the perception that flow experiences could be controllable to some
13 extent, and are not merely 'coincidental'. Additionally, it is appears that physiology is also
14 relevant in flow, and these experiences may be psychophysiological.

15 **Conclusions:** Based on these findings, recommendations are made including the need for
16 researchers to move from description to explanation of flow, the use of new methodologies,
17 greater focus on the role of personality factors, and possible refinements of existing flow
18 theory to be more specific to sport.

21 *Keywords:* athletes, optimal experience, performance, positive psychology, narrative synthesis.

1 evaluation), while a *sense of control* over the performance or outcome of the activity can also
2 be experienced, as can a *transformation of time* (i.e., the perception of time either speeding up
3 or slowing down). Finally, the combination of these eight dimensions led to flow being
4 characterized as an *autotelic experience*, a term Csikszentmihalyi (1975) used to describe these
5 experiences as being enjoyable and intrinsically rewarding¹.

6 Flow states have frequently been associated with elevations in well-being (Haworth,
7 1993), self-concept (Jackson, Thomas, Marsh & Smethurst, 2001), positive subjective
8 experience (Csikszentmihalyi, 1975, 2002) and objective performance (Jackson & Roberts,
9 1992). This intersection of peak performance and peak experience is the crux of the flow
10 experience, and means that flow is extremely relevant in sport. Flow research was adopted into
11 sport in the early 1990s, with the first empirical studies published in 1992 (e.g., Jackson, 1992;
12 Jackson & Roberts, 1992). Since then a body of sport-specific flow research has emerged,
13 including a number of studies which are considered classics in the field (Jackson, 1995, 1996).

14 However, whilst the characteristics of flow have been widely studied, and replicated
15 reasonably consistently, the factors that instigate, maintain, prevent or interrupt flow are much
16 less clearly understood. In fact, “there is a degree of uncertainty as to when flow states occur”
17 (Chavez, 2008, p.71), and these experiences are often perceived to be elusive in sport (e.g.,
18 Aherne, Moran, & Lonsdale, 2011). For example, Jackson (1992) reported that 81% of the 16
19 national champion figure skaters in her sample perceived flow to occur only on rare occasions.
20 Indeed, the experience of flow has been regarded as being one of the least understood
21 phenomena in sport (Jackson & Csikszentmihalyi, 1999).

¹ There appears to be some confusion surrounding autotelic experience; in some instances it is referred to as a ninth flow dimension (e.g., Jackson & Csikszentmihalyi, 1999) and in others, usually outside of sport, it is not seen as a separate or additional component, merely a description of the whole flow experience (e.g., Csikszentmihalyi, 2002; Engeser & Rheinberg, 2008). In sport, the trend has been to include it as a ninth dimension and therefore this review will do the same.

1 Early attempts to review the research regarding peak and flow experiences in sport
2 (Kimiecik & Stein, 1992; McInman & Grove, 1991) were published at the same time as the
3 first studies. Hence these reviews adopted a mainly narrative approach – reviewing and re-
4 stating Csikszentmihalyi’s seminal findings and exploring how they may apply in sport.
5 Therefore, the body of sport-specific flow literature that has emerged since 1992 has yet to be
6 systematically reviewed.

7 Flow is particularly relevant for elite athletes who perform and compete at the highest
8 levels, under the most intense pressure, and with the greatest rewards at stake; therefore even
9 the smallest improvement could have dramatic impacts on success (Nicholls, Polman & Holt,
10 2005). Furthermore, Catley and Duda (1997) found skill level to be significantly related to the
11 experience of flow, while Engeser and Rheinberg (2008) also suggest “it is likely that
12 individuals with higher ability have higher flow values” (p.161). This could be because elite
13 athletes by definition have been involved in their sport for a substantial amount of time
14 (Jackson, 1996), and are regularly involved in the challenging, competitive situations that are
15 suggested to facilitate flow. They may also have developed exceptional mental skills which
16 facilitate flow experiences. Hence in sport-specific flow research to date, “elite athletes have
17 been the population of primary interest” (Jackson & Kimiecik, 2008, p.385).

18 Research has also been conducted in non-elite sport contexts, e.g., recreational sport,
19 physical activity, and exercise (e.g., Catley & Duda, 1997; Jackson, Kimiecik, Ford & Marsh,
20 2001; Stein, Kimiecik, Daniels & Jackson, 1995). Findings have generally concluded that
21 “optimal experience does occur for these kinds of participants” (Jackson & Kimiecik, 2008,
22 p.390), however there could also be differences in how flow may occur or be experienced
23 between these settings. The nature of competition, which is dominant in elite sport, could cause
24 participants to focus more on extrinsic (e.g., results) rather than intrinsic (e.g., flow) aspects of
25 the experience, while it has also been suggested that non-elite sport participants may have an

1 advantage over elite athletes in being more able to control their sporting environment in a way
2 that optimises the quality of their experience (e.g., by more easily manipulating challenge-skill
3 balance; Jackson & Kimiecik, 2008). Therefore research is warranted which begins to compare
4 athletes from varying skill levels and explores if and how flow states vary between settings.

5 As research into flow in sport began relatively recently (e.g., 1992), many studies have
6 been exploratory in nature (e.g., Chavez, 2008; Jackson, 1992, 1995, 1996), adopting a
7 primarily qualitative approach which is more difficult to synthesise concisely than statistical
8 data. Therefore due to space restrictions, this review focused only on elite sport in order to
9 provide specific data to those performing at highest standard, and of whom there is more
10 existing literature available. The elite level also represents the domain from which most can be
11 learnt from an applied perspective, in that individuals in lower levels of participation can learn
12 from elite athletes but it is more difficult for higher-level athletes to learn from lower levels of
13 participants, e.g., recreational athletes. Future comparisons could then be made to sub-elite
14 and/or recreational/health/exercise participants, which could highlight similarities and
15 differences in flow states between levels of participation, e.g., in terms of frequency of
16 experience.

17 Positive psychology emphasizes an applied approach, calling for psychologists to focus
18 on amplifying strengths, developing talent, fostering excellence, and helping individuals to
19 realize their human potential (Seligman & Csikszentmihalyi, 2000). In order to realize this
20 applied and pragmatic philosophy, research into flow should, ideally, deliver useful real-world
21 findings and advice that can be easily implemented – such that athletes might understand the
22 occurrence of flow and perhaps even experience flow with greater frequency and intensity. As
23 such, three issues have received attention in previous literature exploring flow in sport: (i)
24 understanding the experience of flow through the eyes of the elite athlete (e.g., Chavez, 2008;
25 Jackson, 1996); (ii) exploring the factors that influence (i.e., facilitate, disrupt and prevent) flow

1 occurrence (e.g., Jackson, 1992, 1995); and (iii) investigating the potential of controlling and
2 manipulating flow (e.g., Jackson, 1995; Sugiyama & Inomata, 2005). The issue of how exactly
3 flow influences performance is also interesting and currently unclear (see Engeser &
4 Rheinberg, 2008), however this review is interested more in flow itself and not its correlates.
5 One possibility though, which does not appear to have been explored yet, is the relationship
6 between flow and psychological momentum which may shed light on this issue.

7 The systematic review process aims to evaluate and interpret all available research
8 evidence relevant to a particular question (Glasziou, Irwig, Bain & Colditz, 2001); it attempts
9 to be systematic in the identification and evaluation of materials, objective in its
10 interpretation, and reproducible in its conclusions (Smith, 2010). This method provides a
11 powerful tool to establish generalizability of scientific findings and summarize research
12 findings to provide ideas for future research (Mulrow, 1994). A systematic review was
13 deemed to be more appropriate than alternative methods, e.g., meta-analysis, which involves
14 statistical analysis of existing quantitative data (Borenstein, Hedges, Higgins & Rothstein,
15 2011). As discussed, the nature of research into flow in sport has lent itself to qualitative
16 studies which are not compatible with meta-analysis. Where systematic reviews are
17 transparent in the selection of included studies and the decisions are specified clearly, they
18 are not limited to quantitative analysis of the data, and can include some aspect of quality
19 appraisal and interpretation of data, offering an advantage over the “unthinking mechanical
20 nature of meta-analysis” (Torgerson, 2003, p.10). Therefore, the purpose of this study was to
21 systematically review all existing research relating to flow in elite sport. Specifically, this
22 review aimed to summarize existing literature exploring: (i) how flow states are experienced by
23 elite athletes; (ii) how flow states occur, and are influenced, in elite sport; and (iii) the control
24 and manipulation of flow.

25

Approach

1 **Development of Search Strategy**

2 The development of a search strategy within a systematic review is an iterative process,
3 essentially refining a strategy from a series of preliminary searches which are evaluated, and
4 discussed and/or reflected upon (Smith, 2010). To begin this review, a list of key words was
5 created by breaking down the research question (cf. Smith, 2010) and trialled in a preliminary
6 search on the SPORTDiscus database. The returns from this search were then *sampled* (e.g.,
7 every 10th return examined and assessed for relevance), and *mined* for alternative keywords that
8 were most relevant and widely used in the literature (Weed, Coren & Fiore, 2009). Findings
9 from this exploratory search were reviewed, and the process was repeated until the most
10 efficient and effective search terms were identified (i.e., those returning the most relevant and
11 specific studies). This process also identified a number of irrelevant terms which were
12 repeatedly returned (e.g., blood flow) and were therefore noted within the search strategy as
13 'limiters' to be removed from the final results. The list of search terms employed was:

14 Flow AND (State* OR Experienc*)

15 AND

16 (Sport* OR Perform* OR Athlet* OR Exercis* OR Motivat* OR Experienc*)

17 NOT

18 (Blood Flow OR Optic* Flow OR Expirat* Flow OR Ventil* Flow)

19 The databases deemed to be most relevant (based on accessibility and relevance to the
20 topic area), and therefore searched, were SPORTDiscus, PsycINFO, SAGE journals online,
21 INGENTA connect, and Web of Knowledge. Hand searching was also conducted by drawing
22 from the reference lists of identified studies and chapters (e.g., Centre for Reviews and
23 Dissemination [CRD], 2009).

24 **Inclusion/Exclusion Criteria**

1 Inclusion/exclusion criteria were employed to ensure that the boundaries of the review
2 were clearly defined, and that the search strategy would identify all literature relevant to the
3 three key aims of the review (CRD, 2009; Smith, 2010). The studies included in this review
4 needed to: (i) be peer-reviewed research studies; (ii) be published in the English language only;
5 (iii) have gathered original empirical evidence; (iv) be published before August, 2011 (when the
6 formal search was finalized); (v) contain specific references to flow in either the title or
7 abstract; (vi) explicitly relate to elite participants, defined as those competing in the NCAA
8 Division 1 in America (cf. Jackson & Kimiecik, 2008), county level in the UK (cf. Callow &
9 Hardy, 2001), or national level (cf. Sheard & Golby, 2010) *and above*, and either needed to use
10 samples containing entirely elite participants, or a separable/discreet elite sample (e.g.,
11 comparing elite participants to non-elite); (viii) involve sporting activities as defined by the
12 Oxford Dictionary of Sports Science and Medicine (Kent, 2006)²; and (ix) include data that
13 was relevant and compatible with the three aims of this study (e.g., a study using elite
14 participants and mentioning flow, but with no relevance to the aims, could be excluded).

15 **Search Returns**

16 The search process was finalized on 16th August, 2011, and initially returned 12,819
17 potentially relevant studies. After duplicates were removed, and the titles were assessed for
18 relevance, this number was reduced to 156 and the abstract for each article was obtained where
19 possible (no abstracts for empirical or includable studies were unobtainable). 88 studies were
20 then excluded based on assessment of their abstract against the inclusion/exclusion criteria,
21 leaving a total of 68 studies eligible for full-text retrieval. Subsequently 49 studies were
22 excluded, often because they contained non-elite samples, and two further studies were

² Any highly structured, goal directed physical activity governed by rules, which has a high level of commitment, takes the form of a struggle with oneself or involves competition with others, but which also has some of the characteristics of play, and involves either vigorous physical exertion or the use of relatively complex physical skills.

1 excluded for not presenting data that was reconcilable with the aims of the study (i.e., criteria
2 ix). Hence 17 studies met the inclusion criteria.

3 **Data Synthesis**

4 Once the final 17 included studies had been identified, each was repeatedly read in full
5 by the lead researcher in order to become familiar with, and immersed in the data in order to
6 fully appreciate what it was saying (see Maytuk & Morehouse, 1994; *indwelling*). This was
7 followed by a two-stage process of thematic analysis, which “comprises the identification of
8 the main, recurrent or the most important issues or themes arising in a body of evidence. It is
9 typically the method used for identifying, grouping and summarizing findings from included
10 studies” (Pope, Mays & Popay, 2007, p.96). First, deductive analysis was deployed to sort data
11 from different studies into each of the three organizing constructs (experience, influences, and
12 controllability). As CRD suggested: “once the relevant studies have been data extracted, the
13 first step is to bring together, organize and describe their findings” (2009; p50), for which
14 inductive thematic analysis was used. Following this: “there is a clear attempt to explore
15 relationships between: (a) characteristics of individual studies and their reported findings; and
16 (b) the findings of different studies” (CRD, 2009; p.51).

17 The majority of findings were qualitative, which necessitated a more
18 narrative/interpretive approach to synthesis than would be the case for more quantitative data.
19 Hence, a *narrative synthesis* was chosen as it “relies primarily on the use of words and text to
20 summarize and explain the findings of multiple studies...(and) where evidence allows, it can
21 also involve some element of integration and/or interpretation” (Pope et al., 2007; p.102).
22 Narrative synthesis has been suggested to form the middle ground in a continuum from
23 quantitative (e.g., meta-analysis) to qualitative (e.g., meta-ethnography) synthesis approaches,
24 and allows the synthesis of both qualitative *and* quantitative data, as well as the use of a range
25 of techniques (e.g., thematic analysis) because the synthesis is text-based (Pope et al, 2007).

1 **Establishing Trustworthiness**

2 As most data was qualitative and a text-based approach to synthesis was adopted, a
3 number of processes were followed in order to establish trustworthiness and increase
4 objectivity. The term *trustworthiness* has been used by qualitative researchers to describe
5 methods used to meet the criteria of validity, and credibility in their research (e.g., Harrison,
6 MacGibbon & Morton, 2001; Lincoln & Guba, 1985).

7 **Peer debrief.** This process involves the review of data and the research process by
8 someone who is familiar with the research or the phenomenon being explored, and who
9 provides support, plays devil's advocate, challenges the researcher's assumptions, and pushes
10 the researcher to the next step methodologically, including questioning the methods used and
11 the resulting interpretations (Creswell & Miller, 2000; Lincoln & Guba, 1985). This process
12 took place between the lead researcher (first author) and the second, third and fourth authors,
13 who provided guidance on the process of conducting systematic reviews, and of research on
14 flow states in sport. Peer debrief took place throughout this study, by way of regular formal
15 meetings and informal discussions.

16 **Advisory group and audit trail.** In accordance with Weed et al (2009), CRD (2009),
17 and Smith (2010), an advisory group was set up comprising of three external researchers who
18 had previously published studies on flow in sport. Each researcher was contacted and invited to
19 become part of a panel serving to critique and guide the procedures followed in this review and
20 to provide recommendations on how to improve where possible. This process aimed to seek the
21 guidance of experts who had experience in this specific field. A comprehensive audit trail of the
22 preliminary search, the refined formal search strategy, and the returned studies was sent to the
23 advisory panel for verification and suggestions on any relevant material or missing search
24 terms. The panel approved the audit trail and methods employed, and provided

1 recommendations for other possible inclusions, which were compared to the
2 inclusion/exclusion criteria but subsequently did not lead to any further studies being included.

3 **Findings**

4 **General Findings**

5 The 17 papers included in this systematic review comprised a total population size of
6 1194 athletes, made up of 785 males and 409 females. 16 independent samples were included;
7 two of Jackson's studies (1995, 1996) used the same sample of athletes while investigating
8 different topics. In the case of two studies, the whole sample was not included: Canham and
9 Wiley (2003) included an expert and a novice group, so only data relating to the expert group
10 was used; and Bernier, Thienot, Codron & Fournier (2009) included two studies within their
11 paper, but only Study 1 was related to flow. Nine studies contained data relating to how flow is
12 experienced by elite athletes, ten related to its occurrence, and eight related to the control and
13 manipulation of flow. The results of the review are therefore presented in three separate
14 categories, one for each aim, and the subheadings reflect the themes discussed within the
15 papers. Table 1 presents a summary of the participants and methods used in each study, and the
16 relevant aim(s) to which each study pertained.

17 **The Experience of Flow**

18 **Qualitative exploration of flow.** Five studies (Bernier et al, 2009; Chavez, 2008;
19 Jackson, 1996; Sugiyama & Inomata, 2005; Young, 2000) qualitatively explored athletes'
20 perceptions and descriptions of flow states in order to understand what the experience is like.
21 These findings have been summarized in Table 2, which describes the number and percentage
22 of the 114 athletes reporting each of the flow dimensions combined between these five samples.

23 This process essentially identified a ranking within the flow dimensions, i.e., those that
24 were reported most to least. Over 80% of athletes reported *concentration on the task at hand* in
25 their flow states, followed by *action-awareness merging* almost 75% of the time. Conversely,

1 *loss of self-consciousness* and *transformation of time* were both reported by less than 30% of
2 athletes. Not all nine dimensions were present in every flow state (see *number of flow*
3 *dimensions experienced*) and some themes emerged which did not fit into the existing
4 description of flow (see *concepts not fitting with flow dimensions*).

5 In some of these exploratory studies, researchers have tended to introduce and define
6 flow for the participant at the beginning of the interview, often providing a lot of information.
7 For example, Jackson's (1995) athletes were asked to describe an experience that "stood out as
8 being better than average...where they were totally absorbed in what they were doing and that
9 was very rewarding" (p.78), before they were read three quotes illustrating flow, including:

10 My mind isn't wandering, I am not thinking of something else. I am totally involved in
11 what I am doing. My body feels great. I don't seem to hear anything. The world seems
12 to be cut off from me. I am less aware of myself and my problems (Jackson, 1996, p.78)

13
14 Similarly, Sugiyama and Inomata (2005) asked a series of questions including "Have you had a
15 competition experience in which you were completely absorbed in what you were doing?"

16 These authors followed the questions by showing the participant a written description of flow
17 and asking if they had experienced a state which corresponded to that description.

18 **Quantitative measurement of flow dimensions.** Two studies (Canham & Wiley, 2003;
19 Jackson, 1992) used quantitative measures to explore flow experience. Jackson (1992) used an
20 exploratory quantitative flow questionnaire and found mean scores (on a 10-likert scale) of 8.4
21 or above for all of the flow dimensions except loss of self-consciousness, which she suggested
22 may require further subscale development to more adequately address this component of flow
23 in athletes. Canham and Wiley (2003) used an abbreviated Flow State Scale (FSS; Jackson &
24 Marsh, 1996) and found that expert climbers were more likely to report dimensions of
25 automatic performance, unambiguous feedback, clear goals, and time transformation than
26 novices. However, as these studies both used different measures the data cannot easily be
27 reconciled. Furthermore, it has previously been noted that quantitative measures are not as

1 effective at exploring flow as qualitative methods, especially as they attempt to explore an
2 intensely subjective experience by using objective measures (Jackson & Kimiecik, 2008).

3 Two further studies quantitatively investigated the flow experience, including Stavrou,
4 Jackson, Zervas, and Kerteroliotis (2007) who examined intercorrelations between the flow
5 dimensions on the FSS. These authors found a close relationship between the dimensions of
6 challenge-skill balance, clear goals, unambiguous feedback, concentration on the task at hand,
7 sense of control, and autotelic experience, including close relationships between the first three;
8 the flow conditions. These authors suggest that if these results can be generalized, experiencing
9 flow could be associated with high scores in these six dimensions on the FSS, and speculated
10 that the flow conditions perhaps “modulate the rest of flow-experience qualities and represent
11 the preconditions to get into flow” (2007, p.452). Bakker et al (2011) found that environmental
12 resources (e.g., performance feedback and support from the coach) predicted flow during a
13 soccer game. They suggested that this could have been because environmental resources can:
14 (i) boost one’s belief in their ability to succeed and reach their goals; (ii) foster core self-
15 evaluations including optimism, hope, and self-esteem; or (iii) satisfy basic psychological
16 needs, including the need for competence. These findings suggest an important role for
17 feedback in flow experiences.

18 **Number of flow dimensions experienced.** Two studies (Jackson, 1996; Sugiyama &
19 Inomata, 2005) have explored the number of dimensions that occur simultaneously during
20 athletes’ flow experiences: Jackson reported that all athletes mentioned themes which fit into
21 three or more of the nine flow dimensions, while 93% of the sample mentioned themes which
22 fit into five or more of these. Sugiyama and Inomata also found that on average 5.8 of the nine
23 dimensions applied to their athletes’ experiences (although it is neither discussed, nor clear,
24 how an athlete could experience 0.8 of a dimension). On the basis of these two sets of data, the
25 athletes involved have commonly reported experiencing approximately five of the dimensions

1 at a time. However, these findings are not discussed in either case, and it is unclear which
2 dimensions these were, and if there was any consistency between them (e.g., typical
3 combinations which essentially define the quality of the experience).

4 **Frequency of experiencing flow states.** One study (Jackson, 1992) discussed the
5 frequency with which the elite figure skaters in her sample experienced flow, reporting that
6 81% of her athletes did not experience it very often (although no unit of frequency was
7 provided). Reasons given for this included the fact that it was difficult for “everything to be on”
8 (p.177), because it usually only happened in the biggest competitions, and the rarity of being at
9 one with your partner.

10 **Flow and mindfulness.** Two studies (Aherne et al, 2011; Bernier et al, 2009) using elite
11 athletes have explored flow and mindfulness, the non-judgmental focusing of one’s attention on
12 the experience as it occurs in the present moment (Kabat-Zinn, 1994). This concept has its roots
13 in Eastern meditational practice (Bernier et al, 2009), and has only emerged in Western sport-
14 psychology research in the last decade. The link between mindfulness and flow is based on the
15 proposal that mindfulness is linked to present-moment focus, similar to the flow dimension
16 *concentration on the task at hand*. Bernier et al (2009) attempted to explore this link but did not
17 add conclusive data, instead concluding that “it is important to study how mindfulness and
18 acceptance could specifically contribute to the attainment of optimal performance states in
19 various sport contexts” (p.330). Aherne et al (2011) employed an intervention, which is
20 therefore discussed in *Intervention Studies*.

21 **Team flow.** Bakker, Oerlemans, Demerouti, Bruins Slot and Karamat Ali (2011)
22 proposed that team-level flow in soccer could be experienced since players in the same team
23 share some common aspects of experience (e.g., the same opponent, weather, coach) and are
24 highly dependent on each other as they share similar goals (i.e., playing well and winning the
25 match). These authors also suggested that this could be the result of contagion effects, where

1 individual players transfer their own moods and behaviours to other players in their team.
2 Findings showed that perceptions of flow at the team level had a positive relationship with the
3 objective match result in that flow experience was higher when the match resulted in a draw
4 than in a loss (the differences with winning was not significant).

5 **Concepts not fitting with flow dimensions.** Three studies (Bernier et al, 2009;
6 Chavez, 2008; Jackson, 1996) discussed concepts that did not easily reconcile with any of the
7 dimensions proposed by Csikszentmihalyi. Jackson's (1996) athletes reported the concepts:
8 *aware of effort; remember hearing the crowd; feel out of body; and as if watching self.* Notably,
9 Jackson discussed that, although it is proposed that movements in flow seem easy, some
10 athletes were aware of exerting effort, which they found enjoyable in flow. Jackson suggests
11 that the word 'effortless' may not clearly convey what is occurring during flow when it is part
12 of physical activities; instead it may be an absence of strain and tension (i.e., negative
13 emotions/perceptions) rather than an absence of effort *per se*.

14 Furthermore, 56% of Chavez's (2008) participants reported relaxed, calm aspects of the
15 flow experience. It is not immediately clear as to which of Csikszentmihalyi's nine dimensions
16 this idea fits into. This theme also provides an indicator of what athletes may be experiencing
17 physiologically during flow. Indeed, Chavez also found that 68% of the sample indicated that
18 there is a heightened perception of the body in the environment in which the athlete is
19 competing, including examples such as a golfer describing that it felt like his club was an
20 extension of his hand. Similarly, Bernier et al (2009) reported that 60% of the elite swimmers in
21 their sample mentioned a heightened state of bodily awareness, including a strong heartbeat, a
22 "tingling" sensation in their muscles, heat in their extremities, and a feeling of "boiling" inside.

23 **Factors Influencing Flow Occurrence**

24 Five studies (Chavez, 2008; Jackson, 1992, 1995; Sugiyama & Inomata, 2005; Young,
25 2000) explored the factors that athletes reported to have been present when flow occurred,

1 which this review will refer to as facilitators. These factors can occur prior to, or during the
2 performance. Four studies (Chavez, 2008; Jackson, 1992, 1995; Young, 2000) explored the
3 factors that have prevented flow from occurring. Preventing factors must affect flow *before* it
4 can occur in the first place, and may therefore influence the athlete prior to or during the event
5 but before flow can occur. Four studies (Chavez, 2008; Jackson, 1992, 1995; Young, 2000)
6 have explored the factors that disrupt flow. Disrupting factors must occur *while* the athlete is in
7 flow, and effectively take the athlete out of the experience (or reduce the magnitude of the
8 experience), during the event itself. Combined in the synthesis were a total of 12 different
9 facilitators, 10 preventers, and 11 disruptors, all of which are highlighted in Table 3.

10 There is considerable consistency and overlap across the identified influences in that ten
11 factors were found to influence flow as facilitators, preventers, *and* disruptors. The positive or
12 optimal presence of these ten factors facilitates flow, while their presence in negative form
13 inhibits, either preventing if they occur before flow, or disrupting by occurring during flow
14 states. Within this group, the concepts of *focus* and *thoughts and/or emotions* were reported by
15 every study under every category of influence (i.e., facilitate, prevent, disrupt), and therefore
16 could suggest that these are either central to flow experience, or are the easiest to convey.

17 In regard to its occurrence, flow seems to result from the interaction of internal states
18 (e.g., focus, arousal, motivation, confidence, thoughts and emotions), external factors (e.g.,
19 environmental and situational conditions, i.e., weather, or course that suited the athlete) and
20 behavioural factors (e.g., preparation). If any of these factors are in their negative form prior to
21 flow can occur, they prevent the experience, and if they occur in their negative form during the
22 experience flow is disrupted. However, it is difficult to tell whether these influences can act on
23 their own, or in what combinations they interact to bring about or inhibit flow.

24 In some instances the authors do *allude* to causal mechanisms, such as Jackson
25 discussing that preparation or “knowing everything was in place allowed the athlete to focus on

1 the task and to switch into a more automatic mode of functioning that seems to be part of the
2 flow process” (1995, p.147). However, such causal links are not discussed in enough depth or
3 formalised in a way which enables suggestions as to the underlying mechanisms of flow.

4 Overlaps are also noticeable between some facilitators and flow dimensions, both of
5 which refer to the constructs of *concentration*, and *positive feedback*. This overlap seems to
6 have occurred because researchers to date have made a temporal distinction in that facilitators
7 occur *prior* to flow, while dimensions occur *during*, meaning the same constructs have been
8 reported twice. It is also noteworthy that the other two flow conditions, *challenge-skill balance*
9 and *clear goals* were not discussed as facilitators. It has been discussed that these possibly are
10 taken for granted by elite athletes; hence they were not discussed in interviews (e.g., Jackson,
11 1996). Another issue arises in that the facilitators of *optimal motivation*, *optimal arousal*,
12 *confidence*, and *positive thoughts and emotions* all intuitively seem like constructs which
13 individuals could experience as part of the flow state. However it is unclear as to which flow
14 dimensions each of these constructs would be part of.

15 **Further results: Individual differences and flow.** Three studies referred to specific
16 personality traits which were proposed to influence an athlete’s propensity to experience flow;
17 an idea which has been termed “autotelic personality” (e.g., Csikszentmihalyi &
18 Csikszentmihalyi, 1998). Hodge, Lonsdale and Jackson (2009) found that the satisfaction of the
19 basic psychological needs proposed by Ryan and Deci (2002) (i.e., autonomy, competence, and
20 relatedness), and athlete engagement (an enduring, relatively stable sport experience involving
21 positive affect and cognitions about one’s sport as a whole) predicted (using structural equation
22 modelling) dispositional flow. Wiggins and Freeman (2000) found that athletes who interpreted
23 their anxiety as more facilitative and who experienced lower levels of anxiety intensity were
24 much more likely to experience flow than athletes with higher intensity levels and debilitating

1 interpretation of their anxiety. In relation to achievement goal theory (Nicholls, 1989), Jackson
2 and Roberts (1992) reported that athletes high in mastery orientation experienced flow more
3 frequently than athletes low in mastery, while flow was also found to be associated with high
4 levels of perceived ability.

5 **Control and Manipulation of Flow**

6 Four studies (Chavez, 2008; Jackson, 1992, 1995; Sugiyama & Inomata, 2005)
7 explored the controllability of flow states as perceived by elite athletes. These researchers have
8 done so in two ways: first, by asking athletes whether or not they perceived flow to be
9 controllable; and second, by discussing the perceived controllability of the factors found to
10 influence flow occurrence.

11 **Athletes' perceptions of control over flow.** Table 4 below illustrates the findings of
12 these studies in relation to the perceived controllability of flow. On average, 66% of the athletes
13 in these samples perceived flow to be controllable, a figure which rises to 72% if we include
14 those in Jackson's (1992) study who reported flow to be partly controllable. An average of
15 26.5% of participants in the included studies perceived flow to be difficult or impossible to
16 control.

17 **Athletes' perceptions of control over the factors influencing flow occurrence.**

18 Jackson (1995) found that 82.4% of facilitators and just under 70% of preventing factors were
19 perceived to be controllable, while 71.6% of disruptors were seen as uncontrollable, and
20 expanded to note that "this group of elite athletes seem to be saying that they will remain in
21 flow unless some uncontrollable event occurs to take them out of this state" (p.153). Themes
22 that were consistently perceived to be controllable by athletes across two studies (Chavez,
23 2008; Jackson, 1992) included *preparation*, *optimal arousal*, and *positive thinking*. Both studies
24 also referred to factors which influence flow occurrence but with the perception of limited or no
25 control (see Table 4). Some of these findings appear to be contradictory in that certain factors

1 were perceived to be both controllable and uncontrollable, specifically *concentration, optimal*
2 *arousal, motivation, and positive/negative attitude*. Hence it appears that some athletes feel they
3 can control certain factors while others do not, again alluding to a role for individual
4 differences (i.e., it is unclear where the locus of causality lies).

5 **Restoring flow.** Chavez (2008) also investigated the factors associated with reinstating
6 flow after disruption, which 81% of the athletes in his study perceived to be possible. Themes
7 of positive thinking, task orientation, relaxing, clearing mind, thorough performance and
8 building confidence were reported by these athletes as factors that restore flow. This is an
9 interesting and potentially very useful idea, but one which appears to be somewhat novel in that
10 Chavez is the only study to address this theme.

11 **Intervention studies.** Four studies investigated the effects of psychological
12 interventions on flow experience in elite athletes, using slightly different designs. Lindsay,
13 Maynard and Thomas (2005) used a non-concurrent multiple baseline design to examine the
14 effects of a *hypnosis* intervention; Nicholls et al (2005) employed a single-subject replication
15 reversal (ABA) design to examine the influence of an *imagery* intervention; Pain, Harwood and
16 Anderson (2011) used a single-subject multiple baseline design across individuals to examine
17 pre-competition *imagery and music*; and Aherne et al (2011) used control and experimental
18 groups and assessed flow before and after a six-week *mindfulness* intervention.

19 In the cases of Lindsay et al. (2005) and Nicholls et al. (2005), findings were small in
20 magnitude which “makes it unclear whether the changes in flow and performance are due to the
21 imagery intervention” (Nicholls et al., 2005, p.56). Despite this, Nicholls et al. (2005) use a
22 “social validity argument” (p.58) to propose that the small percentage improvements their study
23 produced may actually be significant. Lindsay et al. (2005) also stated that their findings “do
24 not add conclusive support” to the hypothesis that hypnosis interventions can be used to
25 increase flow and performance (p.173), and suggest that “there is also the possibility of a

1 Hawthorne effect, meaning changes in performance might merely be a result of being involved
2 in the investigation” (p.174).

3 In contrast, Aherne et al. (2011) reported that athletes who underwent mindfulness
4 training reported sizeable increases not only in global flow scores but also specifically on the
5 dimensions of “clear goals” and “sense of control” compared to a control group. These authors
6 suggested that both of these dimensions could be related to the self-regulation of attention,
7 which is a key component of mindfulness. While advocating the need for further research
8 employing larger samples, and thus greater statistical power, before firm conclusions can be
9 met these findings seem to provide initial evidence for the potential of enhancing flow. This
10 suggestion is echoed by the findings of Pain et al. (2011) who reported “consistent and sizeable
11 increases” (p.226) in flow when imagery and music were combined during pre-competition.
12 These authors conclude that this combination “generally had a facilitative effect on flow”
13 (p.229), while also noting that further research is needed to confirm their findings.

14 **Discussion and Recommendations**

15 **The Experience of Flow in Elite Sport**

16 The first aim of this systematic review was to summarize existing research exploring
17 how flow states are experienced by elite athletes in order to explore how Csikszentmihalyi’s
18 model applies to elite sport. Findings identified aspects of the flow experience in elite athletes
19 and ranked them in order of prevalence between studies (see Table 2). This variance could be
20 explained by the different variables across sporting contexts (such as type of sport), as noted by
21 Jackson (1996). We do not suggest that this ranking will generalize to all sporting contexts, but
22 it does provide an indication that some dimensions may be experienced more frequently (or
23 more readily reported) than others, or could even be more characteristic of flow experiences.

1 On the basis of the limited data available, athletes reported experiencing approximately
2 five of the flow dimensions at any given time. Although it could simply be the case that athletes
3 did experience the remaining dimensions but did not or could not articulate them to the
4 interviewer, this finding could suggest that there are nine theoretical dimensions that *could* be
5 experienced, but the number and make-up of these that are actually experienced may vary
6 between flow occurrences. This alludes to Csikszentmihalyi's (e.g., 1975) proposed *flow*
7 *continuum* whereby these states can occur as rare, 'macro' flow and everyday 'micro' flow
8 states. However, there is little empirical data examining this proposition in sport, and Jackson
9 (1992) proposed that "further research is needed to clarify whether flow is something
10 experienced only infrequently by top athletes or whether it occurs, to varying levels, on more
11 frequent occasions, for athletes of all levels" (p.177).

12 While data has described how elite athletes experience flow, some ideas also emerged
13 which did not easily reconcile with Csikszentmihalyi's model of flow. The majority of athletes
14 in two studies (Bernier et al., 2009; Chavez, 2008) reported experiencing heightened
15 perceptions of the body, or bodily sensations in flow. Similarly, in Jackson's (1996) and
16 Sugiyama and Inomata's (2005) analyses, themes relating to the body were subsumed under
17 *autotelic experience*, e.g., "endless supply of energy", "body feels great", "no pain", and "feel
18 strong" (although it is also questionable as to whether these should be coded under autotelic
19 experience; see *Methodological critique*). Indeed, recent studies outside of sport have begun
20 exploring this link between flow and physiology: De Manzano, Theorell, Marmat and Ullén
21 (2010) found a significant relation between flow and heart period, blood pressure, heart rate
22 variability, activity of the zygomaticus major muscle, and respiratory depth during piano
23 playing; and Keller, Bless, Blomann and Kleinböhl (2011) identified reduced heart rate
24 variability and higher levels of salivary cortisol during flow in computerised tasks. Therefore it

1 could be the case that flow is not solely psychological, but a psychophysiological phenomenon,
2 and there may be both physiological responses to, and activators of flow, e.g., optimal arousal
3 which was identified as a facilitator.

4 Furthermore, heightened body awareness may only apply to certain sports. For
5 example, the results suggest that for swimmers awareness of their body's state is highly
6 relevant, and could be regarded as being part of the task itself, whereas for sports which need
7 reactions to changing outside stimuli (e.g. tennis, soccer) this may not be the case, and
8 awareness of one's body could even hinder good performance. Other differences in how flow
9 is experienced across settings was also alluded to: Chavez (2008) discusses minor differences
10 in perceived control of flow between athletes from individual and team sports, and also
11 alludes to differences in participation level, while Sugiyama and Inomata (2005) note
12 differences in flow experience between types of sport, namely speed and endurance events.
13 These differences should be explored and compared in future.

14 Bakker et al. (2011) also referred to flow occurring at the team level, and not solely
15 within the individual. It could be possible that players within the team act as a catalyst for
16 others; when the 'catalyst' goes into flow other players on the team follow. It could also be
17 that these players act as the leaders within the team. This may explain why some sports teams
18 can produce exceptional team performances, and could present an interesting area to explore
19 further, e.g., by conducting interviews or focus groups with one team to discuss if they share
20 flow experiences, and exploring the relationship between leadership and flow in sport.

21 **The Occurrence of Flow States in Elite Sport**

22 The second aim of this systematic review was to summarize the existing literature
23 exploring how flow states occur in elite sport; its facilitation, prevention and disruption.

1 Findings suggested that there appears to be one group of ten concepts that generically influence
2 flow occurrence (see Table 3), with *focus* and *thoughts and/or emotions* the most-reported
3 factors. These ten concepts range from internal states (e.g., optimal motivation) to behaviours
4 (e.g., preparation) to external influences (e.g., environmental conditions), suggesting that flow
5 occurs through a complex interaction of different variables. Additionally, it is difficult to know
6 what specifically makes each of these influences ‘optimal’ or ‘negative’, although it could be
7 likely that they depend on individualised perceptions. Hence ideographical research such as
8 Hanin’s (1997) Individual Zones of Optimal Functioning may be useful in exploring this issue
9 in future. However, thus far the identification of these influences is based on associations (i.e.,
10 factors present when flow has occurred previously), and Kimiecik and Stein (1992) note that:

11 It is one thing to know, for example, that a flow experience is accompanied by focused
12 concentration, feelings of control, and clear goals. It is quite another to know why or
13 how the flow experience actually occurred...(and) the mechanisms underlying the
14 experience (p.148).

15 Such underlying mechanisms have been alluded to but not formalised, nor investigated
16 explicitly or thoroughly (see *Factors influencing flow occurrence*). Instead, current
17 understanding remains descriptive and cannot suggest an explanation of flow, and as a result
18 flow states remain to be reported as being elusive and unpredictable (e.g., Aherne, 2011;
19 Chavez, 2008). It also appears that not all of these dimensions and factors are
20 experienced/present during every flow experience and it remains unclear as to why certain
21 factors may be experienced in a certain state but not others. Similarly, there seems to be no
22 evidence suggesting how much of each flow dimension is necessary (e.g., intensity of
23 concentration on the task at hand).

24 Hence researchers should strive to explain how and why flow occurs, particularly in
25 terms of the causal mechanisms that are responsible for producing these experiences. Such
26 mechanisms have not yet been addressed in sport, but could provide important insights into
27 exactly how flow experiences occur, rather than simply describing associations. One possible
28

1 way of exploring such mechanisms could be through the analysis strategies of researchers in
2 qualitative, exploratory studies, which have tended to rely on deductive thematic analysis,
3 categorising similar themes into the nine flow dimensions. An alternative is connecting analysis
4 which involves “identifying actual connections between events and processes in a specific
5 context” (Maxwell, 2004; p.255), and could begin to identify the causal processes and
6 interactions underlying flow.

7 Within the reviewed research, Sugiyama and Inomata (2005) do propose an “Advanced
8 flow model” (p.979) that displays links between the nine dimensions of flow, yet
9 disappointingly these links are not discussed. However, one possible explanation from broader
10 flow research is that of Dormashev (2010), who argues that “prolonged effortless concentration
11 of attention is the principal characteristic of the flow experience” (2010, p.306), and proposes
12 an explanation of flow based on an activity approach to attention. Although this explanation of
13 flow is based on theoretical analysis and is, therefore, preliminary, others have also suggested
14 that flow is the result of unconscious, or automatic, processing (e.g., Pates, Cummings &
15 Maynard, 2002; Singer, 2002). This proposal does seem promising and we recommended that
16 future studies in sport gather empirical evidence that address the efficacy of this explanation.

17 The majority of flow research in sport has focused upon situational factors involved in
18 the experience, while the influence of individual differences has largely been neglected. To
19 compound this, researchers have relied, in many cases, on individual differences to explain
20 inconsistency in their findings, e.g., Jackson (1995, p152), who noted that “optimal arousal
21 level was athlete specific” and Chavez’s (2008) suggestion that “it is imperative to be aware of
22 the individual differences in how athletes experience flow” (p.90). However, such differences
23 have, to date, not been explored or elaborated upon. The consequence is that research can only
24 be descriptive, researchers remain relatively unsure of how flow states vary between
25 individuals, and “individual differences” offers a ready-made (and difficult to query)

1 explanation whenever data contains unexpected variability/variance. Given that flow is a very
2 subjective experience, understanding the influence of individual differences in its causation and
3 experience is arguably vital in order to progress our scientific understanding of this
4 phenomenon.

5 Furthermore, no clear understanding currently exists as to what the proposed autotelic
6 personality actually is in sporting terms, although Jackson and Kimiecik (2008) tentatively
7 proposed “a number of dispositional factors that together could make up something resembling
8 an autotelic personality in sport” (p. 392). These factors were goal orientation, perceived sport
9 ability, competitive trait anxiety and intrinsic motivation, and while the findings of the studies
10 included in this review provide some support to this suggestion, more research is clearly
11 needed.

12 **The Controllability of Flow in Elite Sport**

13 The third aim of this study was to summarize the existing research concerning the
14 control and manipulation of flow in order to assess whether it could be possible to increase the
15 frequency and quality with which flow states occur. The majority (approximately 66%) of
16 athletes involved in the included studies have reported flow to be controllable, or “within their
17 control to achieve” (Jackson, 1995, p.151; see Table 4). Possible mechanisms through which
18 flow could be controlled include *preparation*, *positive thinking*, and *optimal arousal*, although
19 these findings remain unclear because they are based on limited research, and appear to be very
20 individual.

21 While such numerical percentages of athletes’ perceptions of control do provide a
22 useful indication as to the potential controllability of these states, it is perhaps limited in that we
23 do not yet know the extent to which it is controllable, or, more importantly, what the athletes’
24 differences in perception depend upon. To date, studies have devoted very little attention to this

1 topic, even though it arguably holds the potential to significantly improve our understanding of
2 flow occurrence in sport. It also provides an interesting caveat to the idea that athletes do not
3 experience flow very often; a contradiction which highlights the need for researchers to better
4 explain flow occurrence.

5 One possible reason for this contradiction is in the methods in which researchers have
6 gone about exploring controllability: trying to identify which influencing factors are and are not
7 controllable, on the assumption that increasing controllable influences will help enhance flow.
8 However, just because these factors are perceived to be controllable *as well as* related to flow
9 does not mean that they *cause* flow to occur, or guarantee its occurrence. This problem
10 highlights the need to fully understand the mechanisms underlying flow states, in terms of how
11 it is experienced and how it occurs; and *then* such controllable influences could be tested as
12 possible ways of enhancing flow. Additionally, some of the methodological issues underlying
13 flow research (discussed in next section) may have an influence here.

14 At this point in the history of flow research, intervention studies appear to have been
15 relatively unsuccessful, arguably because the existing research has been unable to provide
16 comprehensive working/explanatory models of flow phenomenon (i.e., given the state of
17 research to date evidence, interventions are, by necessity, quite speculative). However, while
18 the intervention studies included in this review do not add conclusive evidence *per se*, they are
19 perhaps promising in that they suggest interventions *could* potentially increase the experience
20 of flow in elite sport. Furthermore, the interventions all involved psychological concepts which
21 have not been strongly linked with the experience or occurrence of flow (i.e., hypnosis,
22 imagery, mindfulness, and music). Intervention studies are likely to improve once an
23 understanding has been accrued regarding the determinants of flow states and the mechanisms
24 through which flow is produced. Further exploration of the idea of restoring flow may also be

1 able to identify specific strategies that athletes can use to restore flow once it has been
2 disrupted.

3 **Methodological Critique**

4 **Procedural methods.** Flow is acknowledged as being notoriously difficult to measure
5 (Jackson & Kimiecik, 2008), and a number of issues are apparent within this literature. Firstly,
6 quantitative measurement of flow has been based solely on the Flow Scales (Jackson &
7 Marsh, 1996; Jackson & Eklund, 2004), namely the Flow State Scale, Dispositional Flow
8 Scale, or an early variation, the Flow Questionnaire (see Table 1). This could mean that the
9 results of this review only reflect Jackson's concept of flow yet, as noted, different
10 interpretations do exist regarding the description of flow (see p. 4). Therefore it may be
11 difficult to confidently generalize the results of this review to settings outside of sport, at least
12 not before these differences in interpretation of flow are addressed.

13 Second, in quantitative studies using the Flow State Scale, questionnaires are often
14 distributed after a certain performance, and any flow state within *that* performance is
15 measured using a Likert scale which also enables low ratings to be provided. Therefore, it
16 could be unlikely that flow is experienced in that specific performance given that flow is so
17 difficult to predict, and it could be difficult to be sure that participants in those studies were
18 truly in a state of flow. In future, researchers could distribute questionnaires after events that
19 are more likely to be optimally-challenging, and therefore more likely to facilitate flow than
20 normal performances, e.g., finals.

21 Finally, in regard to qualitative studies using interviews, the technique researchers use
22 could have had an impact on their results. Commonly, a definition is provided to orient the
23 participant with flow (e.g., Jackson, 1992, 1995; Sugiyama & Inomata, 2005). In some cases
24 though, these definitions are relatively in-depth (e.g., Jackson, 1995), and could bias the

1 resulting accounts provided by participants. In future, qualitative researchers should seek other
2 ways of introducing flow in interviews, or only provide vague definitions which are not likely
3 to influence the participant's account of their own flow experiences. Furthermore, careful
4 consideration should be made to the questions asked during the interview, which can obviously
5 influence results also. For example, Bernier et al (2009) reported that participants "had been
6 particularly mindful of their bodily sensations" (p.320), and that they "spontaneously
7 mentioned a heightened state of bodily awareness" (p.323), but also state in their procedure that
8 the participants were asked to describe in-depth aspects of the experience including their bodily
9 sensations.

10 **Study design.** As research has revolved around exploration and description, the methods
11 employed have developed certain tendencies which, when synthesized, have inevitably resulted
12 in a picture lacking clarity and simplicity. Studies have tended to use samples of athletes
13 combining variables such as sex, sport, type of sport, and ability/skill level in order to describe
14 flow in sport. However combining data from different sports, which all have differing demands,
15 means one little-reported theme present in one study could actually have a great role in flow
16 states for athletes in another study. Furthermore, it could be the case that team sports and
17 individual sports make a difference in how flow occurs and is experienced, or the same with
18 self-paced versus externally paced sports. Future studies should attempt to isolate the
19 determinants/antecedents of flow in order to identify if, to what extent and in what
20 circumstances each variable contributes to flow experiences.

21 In exploring and describing flow, studies have often conducted in-depth interviews
22 discussing previous flow experiences and retrospectively relying on the participant's memory
23 (e.g., Chavez, 2008; Jackson, 1995, 1996). While this tendency has been as argued to be a
24 defensible and appropriate method for gaining exploratory data (e.g., Jackson & Kimiecik,
25 2008), if it becomes the prevalent methodology then the limitations begin to accumulate and

1 produce blind-spots. Perhaps the most notable limitation is that the flow experience discussed
2 in the interview is often chosen by the interviewee and could have been months, even years
3 before the interview, which can reduce the accuracy and precision of the data provided (e.g., the
4 ‘rose-tinted glasses effect’). As such, researchers could seek to reduce the extent to which these
5 interviews are retrospective and aim get closer to flow experiences (e.g., by exploring flow as
6 or immediately after it occurs, or trying to produce flow experience which are then concurrently
7 analyzed). For example, Engeser and Rhienberg (2008) employed such a strategy in education
8 which could be tailored to, or provide guidance for, studies in sport.

9 **Use of Csikszentmihalyi’s flow dimensions.** All studies made explicit comparisons to
10 Csikszentmihalyi’s model of flow, which has been a key framework for research in this area.
11 Indeed, Chavez (2008) was the only exploratory study which did not deductively code data
12 into the flow dimensions. An issue with over-reliance on deductive coding is that findings
13 could essentially be shoe-horned into the flow dimensions, without allowing for evolution or
14 refinement of the theory, e.g., to be more specific to sport. There are also instances where
15 such coding seems questionable, suggesting such a show-horning effect. For example,
16 “endless supply of energy”, “body feels great”, “no pain”, and “feel strong” were coded into
17 autotelic experience (Jackson, 1996; Sugiyama & Inomata, 2005), which is defined as the fun,
18 enjoyable, intrinsically-rewarding aspect of flow (Csikszentmihalyi, 2002; Jackson &
19 Csikszentmihalyi, 1999), and does not seem appropriate. Future studies should consider
20 inductive analysis to let themes emerge from the data, which can *then* be compared to
21 Csikszentmihalyi’s description of flow.

22 Other issues have also emerged from this review, firstly in terms of overlaps between
23 facilitators and dimensions of flow, with *concentration* and *feedback* highlighted in both
24 categories. While it is unclear as to which criteria are used to define the flow conditions, this
25 overlap does seem to suggest that concentration could be a condition of flow rather than a

1 characteristic. Secondly, aspects which seem intuitively to be part of the flow experience (e.g.,
2 optimal arousal, motivation, confidence) were also found as facilitators, which poses two
3 problems. First, it is unclear as to where these constructs fit into the nine flow dimensions. To
4 illustrate, confidence is discussed in relation to three different dimensions (challenge-skill
5 balance, sense of control, and clear goals) by Jackson and Csikszentmihalyi (1999). Second, if
6 they are indeed aspects of the experience, and have also been identified as facilitators, it
7 suggests that these too could be considered as conditions of flow.

8 Hence, it seems that clarification and clearer definition of the conditions and
9 characteristics of flow is warranted. Mackie's (1965) distinction between *necessary* and
10 *sufficient* conditions may be useful in this regard, which could also help researchers begin to
11 explore the causality of flow. Overall, however, these findings suggest that flow theory should
12 be at least critically evaluated before being adopted as a framework for investigating flow in
13 sport, and that there could be an opportunity to take steps "towards refining
14 Csikszentmihalyi's...model of flow to more specifically describe flow in sport environments"
15 (Jackson, 1996, p.85). Such refinements could also include consideration for physiological
16 aspects of flow.

17 **Limitations**

18 Because the procedures in a systematic review are explicit and transparent, the values
19 used to inform the review should be open to criticism and comment (Torgerson, 2003); hence
20 it is important to note some of the possible flaws within the adopted approach. Some findings
21 are based on the reports from only one or two papers, and the review process inevitably
22 identifies studies that are diverse in their design, methodological quality, specific
23 interventions used, and types of athletes studied; all of which may affect validity.
24 Additionally, the inclusion/exclusion criteria employed may have excluded literature which

1 could have been relevant to answering some of the aims of this review, but did not meet all
2 criteria, for example, relating specifically to elite sport. However, some of these issues (e.g.,
3 the limited number of studies available in certain sections) are unavoidable due to the nature
4 (and limited amount) of research in the area which this review was synthesising.
5 Furthermore, as a narrative approach to synthesis was adopted, procedures of enhancing
6 trustworthiness were also employed (e.g., peer debrief, audit trail, advisory group) which
7 aimed to overcome, or at least minimise, such issues.

8 A final limitation is that there is no comparison group within this review (i.e., the focus
9 was solely on elite athletes) and it is also interesting to question whether flow is experienced
10 by individuals performing on a lower level, such as sport beginners or participants of health-
11 oriented sports courses. It could be the case that different flow characteristics are dominant,
12 the flow experience could be facilitated by different factors, or experts could control flow
13 better than beginners (or vice versa). By presenting a review of elite sport, future research can
14 make comparisons between elite and lower level participants (e.g., by conducting a similar
15 review on non-elite sport).

16 **Applied Recommendations**

17 Although the emphasis should be on developing clear understanding and explanation of
18 the phenomenon, practitioners may be able to use the findings emerging from this review to
19 suggest ways of promoting flow in their athletes. Specifically, we suggest a multi-faceted
20 intervention, including psychological, physical and social factors, may be the most appropriate
21 approach, rather than testing the influence of a single mental skill on flow (as has been the case
22 to date). The skills involved should be matched to the causal influencing factors and
23 dimensions of flow, and the personality characteristics of the individual. Based on the present
24 findings, these could revolve around thorough preparation, task-focus, coping strategies, goal-

1 setting, motivational exercises, confidence building, and arousal manipulation. These exercises
2 may initiate flow, but could also help the athlete restore flow, in line with Chavez's (2008)
3 findings (see *Restoring flow*). Such an intervention does not yet appear to have been conducted
4 in elite sport, but could be designed, tested and refined based on the findings of this study.

5 **Conclusion**

6 The exploration of flow in elite sport has only occurred relatively recently, with the first
7 studies published in 1992. Since then, the area has grown and a relatively in-depth description
8 of flow has been developed. Elite athletes experience the nine flow dimensions with varying
9 frequency and research has developed a comprehensive impression of what it is like for these
10 athletes to experience flow (Jackson, 1996). A set of ten factors have been found to influence
11 flow in terms of facilitating, preventing, and/or disrupting; leading to the possibility that these
12 could be the essential "ingredients" in producing flow. Finally, despite its anecdotal reputation
13 of being elusive, and research suggesting athletes do not experience it frequently (Jackson,
14 1992), the majority of athletes participating in the studies sampled perceived flow to be within
15 their control, at least to some extent. However for knowledge to progress, we argue that
16 research should move from such description to *explaining* flow, and explicitly searching for its
17 underlying causal mechanisms. We also suggest there are opportunities to refine
18 Csikszentmihalyi's flow model to be more specific to sport, and methodological issues which
19 researchers can overcome to provide clearer, more specific data.

20 The possibility of being able to enhance the frequency and quality of an elite athlete's
21 flow experiences is exciting for practitioners and the athletes themselves, especially in terms of
22 the potential of improving performance. By building towards an explanation of flow and its
23 occurrence, this possibility becomes greater: the more researchers understand flow and can
24 explain it, the greater chance they have of delivering effective applied recommendations and

1 interventions to athletes, and of enhancing their performance and experience within sport to the
2 highest levels possible.

1 Table 1: Summary of participants and methods used in the included studies.

Study	Participant information	Design	Method	Study aim
Aherne, Moran & Lonsdale (2011)	13 (9male, 4 female) national/international level athletes from 7 sports. <i>M</i> age = 21.00, <i>M</i> years participation = 8.69.	Mindfulness intervention	Flow State Scale-2 (FSS-2) and Cognitive and Affective Mindfulness Scale-Revised.	E,C
Bakker, Oerlemans, Demerouti, Bruins Slot & Karamat Ali (2011)	398 (male) players from 15 Dutch professional soccer clubs (reserve, 16-18, and 14-16 year old teams). <i>M</i> age = 17.5, <i>M</i> time in current team = 10.4 months.	Correlational study	Players completed questionnaire about environmental resources, flow (FSS) and performance during a particular match. Coaches rated players' performance during same match via questionnaire afterwards.	E,O
Bernier, Thienot, Codron & Fournier (2009; Study 1)	10 (4 female, 6 male) elite swimmers at French national training centre; 7 had competed at international level. <i>M</i> age = 20.23.	Descriptive investigation	Semi-structured qualitative interviews describing flow experiences.	E
Canham & Wiley (2003; expert group)	7 (male) climbers with at least 3 years' experience and climbed at least a 5.10a level or harder. <i>M</i> age = 30.1.	Quasi-experimental design	Pre-experiment abbreviated FSS, memory task, two climbing routes, self-report measures of enjoyment, memory, experience of climbs.	E
Chavez (2008)	16 (9 female, 7 male) NCAA Div.1 athletes from 6 sports; 7 had competed at international level. <i>M</i> age = 20.	Descriptive investigation	Lead and follow-up interview discussing factors perceived to facilitate, prevent, disrupt, and reinstate flow, plus those athletes perceived to be controllable.	E,O, C
Hodge, Lonsdale & Jackson (2009)	201 (121 female, 80 male) athletes from 51 sports who received funding from Canadian Sport Centre. <i>M</i> age = 22.92, <i>M</i> years participation = 9.52	Correlational study	Athlete Engagement Questionnaire, Dispositional Flow Scale-2 (DFS-2), basic needs satisfaction questionnaire. Structural equation modelling used.	O
Jackson (1992)	16 (9 female, 7 male) national champion figure skaters; all had competed at world level. <i>M</i> age = 25, <i>M</i> skating experience = 13 years.	Descriptive investigation	Interview examining possible antecedent, preventing and disrupting flow factors. Exploratory Flow Questionnaire assessed components of flow.	E,O, C
Jackson (1995)	28 (14 male, 14 female) athletes from 7 sports who had achieved at least a top 10 placement in international competition. <i>M</i> age = 26.	Descriptive investigation	Interview on factors perceived to have helped or hindered athletes from getting into flow, disruption of flow, and controllability of flow.	O,C
Jackson (1996)		Descriptive investigation	Interview on athletes' experience of flow	E
Jackson & Roberts (1992)	200 (110 male, 90 female) Div.1 college athletes from 8 individual sports. <i>M</i> age = 19.4, <i>M</i> years competitive involvement = 8.	Correlational study	Questionnaire assessing master and competitive goal orientations, perceived ability, flow, and experience in best and worst competitive performances.	O
Lindsay, Maynard & Thomas (2005)	3 (2 male, 1 female) cyclists carrying UK ranking ranging from 1-28. <i>M</i> age = 25.3, minimum competitive experience = 4 years.	Hypnosis intervention	FSS and British Cycling Federation performance measures.	C
Nicholls, Polman & Holt (2005)	4 (3 male, 1 female) amateur golfers with handicaps of 0 to +1 who had competed at county, national or international level. Age range = 20-23	Imagery and music intervention	FSS, position-specific performance measures, Brunel Music Rating Inventory-2, Movement Imagery Questionnaire.	C
Pain, Harwood & Anderson (2011)	5 (male) soccer players previously coached at English professional clubs. <i>M</i> age = 20.9.	Imagery intervention	FSS-2, DFS-2, and individual golf performance measures.	C
Stavrou, Jackson, Zervas & Karteroliotis (2007)	220 (112 male, 108 female) athletes from 7 individual sports, competing at national or international level. <i>M</i> age = 19.95, <i>M</i> competitive experience = 6.98 years.	Correlational study	Challenges and skills measured before and after competition, FSS measured flow after competition, subjective and objective measures of athletes' performance assessed.	E,O
Sugiyama & Inomata (2005)	29 (25 male, 4 female) university and semi-professional athletes from 3 sports competing at national or international level. <i>M</i> age = 20.6, <i>M</i> experience = 10.5 years.	Descriptive investigation	Semi-structured interview examined psychological elements of flow experienced during competition, and explored the psychological states leading to flow experience.	E,O, C
Wiggins & Freeman (2000)	13 (female) Div.1 college volleyball athletes. <i>M</i> age = 19.08.	Correlational study	Observations, Competitive State Anxiety Inventory-2D prior to competition, FSS after competition.	O
Young (2000)	31 (female) professional tennis players. <i>M</i> age = 22.7, <i>M</i> years participation = 12.2.	Descriptive investigation	Self-report instrument combining qualitative (factors perceived to influence flow) and quantitative (FSS, Experience Questionnaire, ratings of challenge, skill, and frequency of flow) measures.	O

2 Note: (E) = the experience of flow; (O) = the occurrence of flow; (C) = controllability of flow.

Table 4: Perceived controllability of flow

Perceived Controllability	Jackson (1992)	Jackson (1995)	Sugiyama & Inomata (2005)	Chavez (2008)
	Participants: 16	Participants: 28	Participants: 29	Participants: 16
Controllable	7 (43.75%)	22 (79%)	21 (71%)	11 (69%)
Partly Controllable	4 (25 %)			
Difficult to Control			8 (29%)	5 (31%)
Uncontrollable	4 (25%)	6 (21%)	None said impossible to control	
Other	2 (12.5%) uncommitted			
Explanations Provided	<p>Controllable facilitators: being well-trained, maintaining appropriate focus, channelling energies/staying relaxed, confidence/positive thinking, enjoying what one was doing, and surrender (not actively trying to control).</p> <p>Uncontrollable facilitators: physical state/how feeling physically on the day, performance of partner, partner unity, crowd response, and "everything being in place".</p>	<p>"It was not possible to determine what was behind this range of perceptions regarding the controllability of flow" (p.153).</p>	<p>Reasons given for control being difficult included "difficulty in producing proper tension, difficulty controlling one's state when not on a big stage, and difficulty producing such a state as it always seems to come from when there is pressure on external sources" (p.977).</p>	<p>Perception of controllable factors: Preparation, positive thinking, optimal arousal, task orientation, motivation, concentration.</p> <p>Perception of limited or no control: Environmental and situational factors, optimal arousal, negative attitude, concentration, motivation.</p>

26 Note: We acknowledged that Jackson's (1992) percentages add up to 106.25%, however this was not explained in the original study.
