Running title: Mirror therapy: a potential intervention for pain management
Mirror therapy: A potential intervention for pain management

ABSTRACT

The consequences of chronic pain and associated disabilities to the patient and to the health care system are well known. Medication is often the first treatment of choice for chronic pain, although side effects and high costs restrict long-term use. Inexpensive, safe and easy to self-administer non-pharmacological therapies, such as mirror therapy are recommended as adjuncts to pain treatment. The purpose of this review is to describe the principles of use of mirror therapy so it can be incorporated into a health care delivery. The physiological rational of mirror therapy for the management of pain, and evidence of clinical efficacy based on recent systematic reviews are also discussed. Mirror therapy, whereby a mirror is placed in a position so that the patient can view a reflection of a body part, has been used to treat phantom limb pain, complex regional pain syndrome, neuropathy and low back pain. Research evidence suggests that a course treatment (4 weeks) of mirror therapy may reduce chronic pain. Contraindications and side effects are few. The mechanism of action of mirror therapy remains uncertain, with reintegration of motor and sensory systems, restored body image and control over fear avoidance likely to influence outcome. The evidence for clinical efficacy of mirror therapy is encouraging, but not yet definitive. Nevertheless, mirror therapy is inexpensive, safe and easy for the patient to self-administer.

Key words: chronic pain, mirror therapy, self-management
Terapia com espelho: potencial intervenção para o manejo da dor

RESUMO
Frequentemente o tratamento medicamentoso é a primeira escolha para o manejo da dor crônica, apesar de efeitos colaterais e alto custo restringirem o tratamento prolongado. Terapias não farmacológicas que sejam baratas, seguras, e fáceis de autoadministrar, como a terapia com espelho, são recomendadas como adjuvantes no tratamento da dor. O objetivo desta revisão é descrever o uso da terapia com espelho para que possa ser incorporada aos protocolos de tratamento de dor. A fisiologia do efeito analgésico da terapia com espelho e a evidência baseada em revisões sistemáticas recenentes são discutidas. Terapia com espelho, em que um espelho é posicionado para que o paciente veja o reflexo de uma parte do corpo é utilizada para tratar dor fantasma, síndrome dolorosa complexa regional, neuropatias e lombalgia. Evidência sugere que o tratamento prolongado (4 semanas) com terapia com espelho reduz a dor crônica. São poucas as contra indicações e os efeitos colaterais. Não se sabe com clareza o mecanismo de ação da analgesia gerada pela terapia com espelho, sendo a reintegração dos sistemas motor e sensorial, a normalização da imagem corporal e o controle sobre a dor e a evitação do movimento possíveis influências no resultado. A evidência para eficácia clínica da terapia com espelho é encorajadora, além da terapia ser considerada barata, segura e facilmente autoadministrada.

Palavras-chave: dor crônica, terapia com espelho, autocuidado
Introduction

Chronic pain is a global healthcare problem affecting developed and developing countries. A systematic review estimated that the weighted mean prevalence of chronic pain in the adult population worldwide may be as high as 30.3% (19 studies, 65 surveys, 34 countries, and 182,019 respondents).\textsuperscript{1} Data from Brazil suggests that the prevalence of chronic pain in the adult population can be as high as 42%.\textsuperscript{2} The economic burden of chronic pain is greater than many other illnesses and diseases because of the high cost to health care and to social security services.

Pharmacological interventions are most commonly used as the first line treatment for chronic pain, although side effects and high costs mitigate long-term use. For example, chronic use of acetaminophen may cause hepatotoxicity; NSAIDs may cause gastrointestinal renal disturbances and a risk of bleeding; and opioids may cause respiratory depression, urinary retention, constipation, nausea and cognitive impairment. Rehabilitation techniques are often used as standalone treatments or as adjuncts to pharmacological treatments and include physical activity and exercise, manual therapy, acupuncture, thermal therapy and electrotherapy such as transcutaneous electrical nerve stimulation (TENS).\textsuperscript{3} The World Health Organization supports the use of rehabilitation techniques that are inexpensive, safe and easy to self-administer will reduce healthcare costs and empower individuals to manage their own pain which is known to improve outcome.\textsuperscript{3}

A rehabilitation technique which has shown promise in recent years is mirror therapy, whereby a mirror is placed in a position so that the patient can view a reflection of a body part. Mirror therapy is most commonly used to relieve pain in limbs by hiding the painful limb behind the mirror (out of view) whilst the non-painful limb is placed in front of the mirror so that it creates a reflection that can be seen by the patient. Thus, the patient can observe a reflection of the non-painful limb so that it appears to be in the same position as the painful limb (out of view) (Figure 1). In amputees this creates the illusion of having two intact limbs.\textsuperscript{4} In individuals with inflamed limbs that appear swollen and red (e.g. complex regional pain syndrome) it creates the illusion of having a ‘healthy-looking’ limb.\textsuperscript{5} Often patients are reluctant to move painful limbs creating pain
behaviours dominated by fear and avoidance of movement. Mirror therapy can be used to create a reflection of a normally moving healthy limb that is located in the same place in space as the painful limb hidden behind the mirror. This gives the illusion that the painful limb can move normally too.

Mirror therapy can be used as a standalone therapy or in combination with other pain relieving techniques. Mirror therapy has been incorporated into therapeutic programs to treat painful conditions resulting from neuropathy complex regional pain syndrome, and non-specific mechanical back pain. It has also been used to improve functional outcomes after stroke.

Mirror therapy is not frequently used to treat chronic pain in Brazil, although it has been suggested that mirror therapy could be inserted in a continuous rehabilitation program to modify behaviour to improve movement and alleviate pain.

The purpose of this review is to describe the principles of use of mirror therapy so it can be incorporated into a health care delivery. The physiological rational of mirror therapy for the management of chronic pain, and evidence of clinical efficacy based on recent systematic reviews are also discussed.

Principles of use
During mirror therapy the patient should be seated comfortably with the mirror positioned between their affected and unaffected limbs. Patients are asked to align the reflection of their unaffected limb with the position of their affected limb, so that the reflection appears as if it is in the same location as the affected limb hidden behind the mirror. The mirror should be sufficiently large to observe the reflected limb whilst it moves without observing the limb behind the mirror. Rehabilitation departments usually have mirrors with stands. Portable mirrors can be used instead, they are relatively inexpensive and can be purchased over the counter and via the internet without prescription at a cost of approximately US$10,000. It is important that the mirror
is easily accessible to encourage the patient to use it, and of a good reflection quality and not bent to prevent blurry or distorted reflections. It is advisable to remove jewellery from limbs as much as possible before treatment.

Treatment begins with an adaptive phase, where patient looks at the reflection without moving the limbs. The reflection of the healthy limb may feel as if it has been perceptually embodied into patient’s body schema so that they get a sense that the reflected limb is their real limb. Perceptual embodiment is the subjective sense of one’s body, including a sense of ownership of body parts. Some patients have difficulty experiencing embodiment, and in this situation the therapist can facilitate the process by instructing the patient to imagine that they are looking through a glass instead of a mirror. Another option is to start with a passive sensory stimulus with slow and easy to achieve bilateral movements whilst the patient observes the reflection. Then the therapist encourages the patient to move their affected limb, which is hidden from view, in synchrony with the unaffected limb. For those where movement of the affected limb is not possible, or if pain or stiffness limits the duration of movement, the patient should just look at the reflected image of the unaffected limb until the patient feels ready to progress to movements. Patients are told that outcomes improve by regularly repeating the technique over time and are encouraged to perform mirror therapy daily as part of a self-administered home treatment programme. Mirror therapy should be performed little and often, for example, five minute sessions, five to six times per day. A single half hour session once a day or once a week is not encouraged. A diary where the patient documents time using the mirror, types of movements, symptoms and outcomes can be a useful aid to sustain adherence to the treatment regimen. Side effects to mirror therapy are motor extinction, increased pain, exacerbation of movement disorders, confusion and dizziness. Treatment is discontinued and contraindicated if any of these occur during a course of mirror therapy.

**Physiological rationale**

Mirror therapy was first described in 1995 by Ramachandran et al. They used a mirror to create the illusion that an amputated limb appeared fully intact when an individual
observed a reflection of their intact limb in a mirror (i.e. mirror visual feedback). Generally, reflections of normal-sized limbs are used, although mirrors, lenses, binoculars and virtual reality have been used to magnify and minify the visual appearance of painful body parts.\\(^\text{12}\) Mirror therapy is commonly used to decrease anxiety, fear of movement and perceived threat associated with movement of painful body parts. This is achieved by creating a visual illusion of a normally moving healthy limb located in the same place in space as the painful limb hidden behind the mirror. The visual feedback of a normal moving limb breaks the link between pain and fear of movement.\\(^\text{6, 8}\)

It has been suggested that pain relief associated with mirror therapy results from manipulation of sensory and motor integration within the central nervous system.\\(^\text{4, 8}\)

During movement, sensory information is used to compare intention with performance and motor commands are updated to adjust for discrepancies, ensuring movement matches intention. Motor signals associated with intended movement are not only sent to muscles but also to higher centres within the central nervous system, as an efference copy, to prepare for the consequence of the motor output and to compare with sensory information arising from actual movement. It has been suggested that some painful conditions can be mediated, in part, by incongruence of sensory and motor information. Mirror therapy provides corrective sensory feedback to restore congruence between motor output and sensory input.\\(^\text{4, 8}\)

Mirror therapy has also been used to correct disruptions of body image (body schema) associated with pain when for example, patients feel as if body parts are large, twisted, heavy and swollen (e.g. complex regional pain syndrome and phantom limb pain) or small and withered (e.g. osteoarthritic hands).\\(^\text{13}\) Research suggests that painful disruptions in body image are associated with re-organisation of neural circuits in the brain due to disrupted somatosensory input from the body part. Mirror therapy is used...
to provide a corrective visual representation of the affected body part to facilitate reorganisation of brain circuits back to their pre-pain state.\textsuperscript{8, 13} Mirror therapy can be used to create a sense of a healthy limb. Painful conditions disturb body image and disrupt an individual’s sense of ownership of their painful body part.\textsuperscript{13} A sense of ownership of body parts has been investigated using the rubber hand illusion whereby an individual observes a rubber hand being stroked with a brush (in view) whilst their real hand is stroked in synchrony but out of view. Eventually, usually within a few minutes, the sensation of stroking feels as if it arises from the rubber hand and the individual experiences a sense that the rubber hand is part of their body (i.e. embodiment of the rubber hand into the body schema). Embodiment of the rubber hand is accompanied by a sense of ‘loss’ (disembodiment) of the real hand and it is accompanied by physiological responses such as local skin cooling, proprioceptive drift and alterations of neural activity in the brain.\textsuperscript{13} The use of mirror therapy to induce the embodiment of the healthy reflected limb may help to disembodify the painful limb, thereby reducing sensory input and pain.\textsuperscript{5}

**Clinical efficacy**

According to Grant and Booth\textsuperscript{14} our review is classified as an Overview, which is a summary of the medical literature that attempts to survey the literature and describe its characteristics. Recently, a number of systematic reviews of randomised controlled clinical trials (RCTs) evaluating the effect of mirror therapy on pain have been published. A summary of the studies included in the systematic reviews is provided in table 1.

[Insert Table 1 here]

The first systematic review to be published was inconclusive due to heterogeneity and low quality of included studies.\textsuperscript{15} Rothgangel et al.\textsuperscript{15} included six RCTs evaluating the effect of mirror therapy on phantom limb pain, complex regional pain syndrome and pain after stroke. Four of these RCTs (123 participants) evaluated mirror therapy as a standalone treatment and all found pain reduction compared with covered mirror
control, mental practice or direct observation of the affected limb.\textsuperscript{16-19} Two RCTs (64 participants) used mirror therapy in combination graded motor imagery techniques such as limb laterality recognition and mental practice and both found a reduction of pain intensity compared with usual physiotherapy care.\textsuperscript{20, 21}

The first meta-analysis of data from RCTs evaluating mirror therapy was conducted as part of a larger review on the effects of graded motor imagery.\textsuperscript{22} Bowering et al.\textsuperscript{22} concluded that graded motor imagery and mirror therapy alone may be effective for a variety of chronic pain conditions. The meta-analysis consisted of data from 3 RCTs (86 participants) and found no effect of mirror therapy on pain when used as a standalone treatment (p=0.07). Control groups included direct view of both hands\textsuperscript{23} and covered mirrors.\textsuperscript{16-18} When used in combination with graded motor imagery, mirror therapy was found to produce a large effect size (standardised mean difference = 1.06; 95% CI, 0.41, 1.71; p = 0.001) on pain reduction in comparison to usual physiotherapy care (63 participants).\textsuperscript{20, 21}

More recently, Thieme et al.\textsuperscript{24} published a systematic review with a meta-analysis of data from eight RCTs (224 participants), including five additional RCTs to the previous review.\textsuperscript{22} Conditions included complex regional pain syndrome,\textsuperscript{25} phantom limb pain\textsuperscript{18, 26} and pain after stroke.\textsuperscript{16, 17, 19, 23, 27} Results indicated that mirror therapy reduced pain in the affected limb (standardised mean difference = -1.00; 95% CI, -1.77 to -0.24; p =.01) when compared with covered mirror, direct view of both limbs, no treatment, and repetitive transcranial magnetic stimulation.

Boesch et al.\textsuperscript{7} meta-analysed data from 1 RCT, 1 non-randomised controlled trial and 1 within subject comparison study (97 participants) to evaluate the effect of one session of mirror therapy on phantom limb pain\textsuperscript{28, 29} and complex regional pain syndrome.\textsuperscript{30} Boesch et al.\textsuperscript{7} did not detect differences from no treatment or covered mirror controls, but their meta-analysis of two RCTs on the effect of a course of mirror therapy lasting 4 weeks resulted in a large significant reduction (standard mean difference= -1.11; 95%CI,-1.66 to -0.56; p < 0.0001) in phantom limb and complex regional pain syndrome compared with covered mirror therapy.\textsuperscript{16, 18} The analgesic effect of mirror therapy was maintained over time ranging from 2 to 6 months.
A RCT of 30 individuals with complex regional pain syndrome has been published after these systematic reviews and the authors concluded that mirror therapy, when used as an adjunct to conventional stroke rehabilitation over the course of 4 weeks, reduced pain intensity when compared to conventional stroke rehabilitation alone. There are also RCTs on the efficacy of mirror therapy for back pain, although there are no systematic reviews to date. Wand et al. placed one large mobile mirror in front of the participant and one mirror behind the participant so that the participant had a clear view of the reflection of their back. They found that pain intensity was reduced immediately post exercise compared with no reflection control during repeated lumbar movements (mean difference = 9.3mm; 95% CI, 2.8 to 15.7; p = 0.007; 25 participants). The duration of low back pain elicited was also shown to be significantly reduced in the mirror condition (mean difference = 49.9s; 95% CI, 19.3 to 80.6; p = 0.003).

Conclusion
Mirror therapy has been used in clinical practice for over two decades, although it is still not widely accepted as a treatment option in Brazil. At present, there are no evidence-based treatment protocols for mirror therapy to be used in clinical settings because of a lack of studies investigating clinical indications, treatment duration and frequency, or characteristics of mirror therapy intervention. This means that techniques are likely to vary considerably between practitioners and patients. Evidence for clinical efficacy is encouraging but not yet definitive. Nevertheless, mirror therapy is inexpensive, safe and easy for the patient to self-administer following initial training. Contraindications and side effects are few. These characteristics make mirror therapy a potential treatment option for pain management.
