Document Version:
Conference or Workshop Item (Published Version)

The aim of the Leeds Beckett Repository is to provide open access to our research, as required by funder policies and permitted by publishers and copyright law.

The Leeds Beckett repository holds a wide range of publications, each of which has been checked for copyright and the relevant embargo period has been applied by the Research Services team.

We operate on a standard take-down policy. If you are the author or publisher of an output and you would like it removed from the repository, please contact us and we will investigate on a case-by-case basis.

Each thesis in the repository has been cleared where necessary by the author for third party copyright. If you would like a thesis to be removed from the repository or believe there is an issue with copyright, please contact us on openaccess@leedsbeckett.ac.uk and we will investigate on a case-by-case basis.
The insular glutamatergic system in Alexithymia: A combined fMRI and MRS study.

Introduction

Alexithymia (AL) is an emotion dysfunction mainly characterized by difficulties in describing and identifying your own emotions. A recent theory suggests that alexithymic features are the outcome of an interoceptive failure.

Interoception refers to the sensation of internal bodily signals, which is supported by the insular cortex (IC) and guides emotional feeling states.

Indeed, AL was found to show aberrant insular activation, in studies using functional magnetic resonance imaging (fMRI)[1,2]. This finding was also corroborated by results of study using Magnetic Resonance Spectroscopy (MRS) showing an association between AL and enhanced insular glutamatergic levels[3].

Objective: Investigating the relationship between neural correlates of Alexithymia and Interoception, using a combination of fMRI and MRS.

Methods

Participants & Procedure
11 male participants (Age: M=24.82; SD=4.45) filled in the Toronto Alexithymia Scale (TAS-20), afterwards they were asked to perform a task (Figure 1) during fMRI scanning. Finally, after the fMRI session, a MRS scan was done.

fMRI Task

Protocol and Preprocessing
Event-related design, including 64 pictures of hand in painful context and 64 pictures of hand in non painful context[4,5]. ~900 volumes were obtained using a T2-weighted multiband echo planar imaging (EPI) sequence; TR=1379ms, TE=42ms, flip angle 90°. All functional images were slice-time and motion corrected, unwarped, coregistered to participants’ individual structural volume, and spatially normalised. Contrast images were computed for the interaction for No Pain*TAS-20.

MRS Protocol and Preprocessing
Spectrum was acquired with a Point Resolved Spectroscopy (PRESS) sequence; TR=2000ms, TE=40ms, flip angle 90°, FOV=16 cm. A volume of interest (VOI) and a shim box of 10x15x25 mm were placed in the right anterior insula using sagittal and a coronal T1 3D volumes (Figure 2). Spectra were analysed using Tarquin and concentration of Glutamate was obtain as ratio to water. The same scanner was used.

Statistical Analyses
Non-parametric two-tailed correlations between questionnaire scores, behavioural ratings, insular activations and glutamate concentrations were computed, using SPSS 22.

Results

Behavioral data
A positive correlation was observed between ratings of painful pictures and AL (τ =0.49, p<0.05).

fMRI data
In No Pain condition, the activation of a cluster in the right IC was positively correlated with AL (τ =0.60, p=0.01) and the factor 1 of the TAS-20 (difficulties describing emotions ; τ =0.64, p<0.01; Figure 3).

MRS data
Glutamate concentrations of the right mid insula were positively correlated with scores of the factor 2 of the TAS-20 (difficulties identifying emotions; τ =0.57, p<0.05; Figure 4).

Conclusion

- Alexithymia is related to a hyper excitability of the insular cortex at functional which seems subtended.
- This hyper excitability seems to be subtended by an increased glutamate concentration.
- This conclusion is in line with the emergent literature supporting alexithymia as the outcome of an interoceptive failure.
- Interoception seems to be disrupted in various clinical and subclinical psychiatric populations, and should be subject of further studies.

- New therapies targeting interoceptive processes should be developed.
